AA 2020-2021

- Big Bang
- Recombination
- Dark Ages
- Formation of stars, galaxies and QSOs
- Reheating and reionization

The IGM

# $z=19.9$

## Simulation

32 Mpc/h box

17,000,000 gas particles

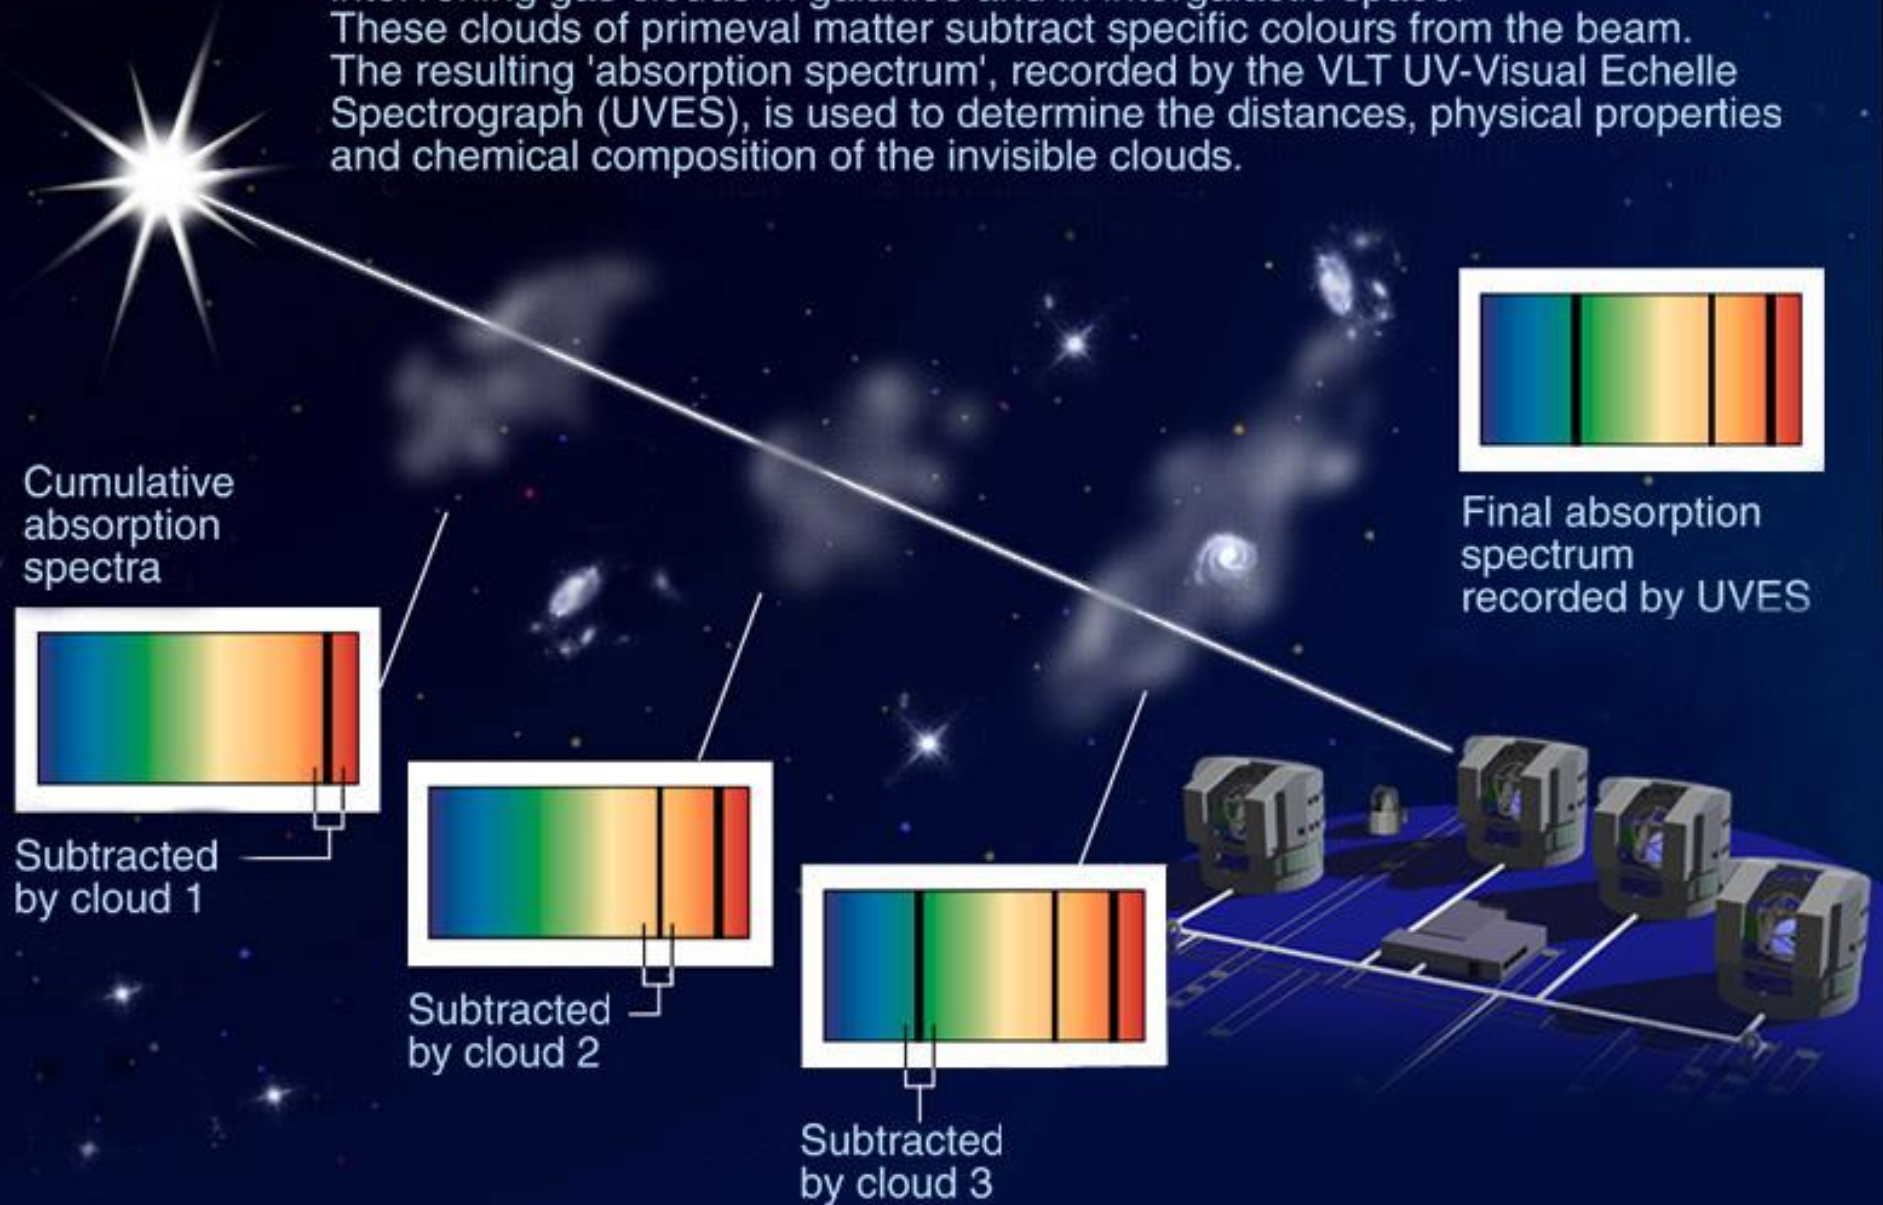

Momentum-driven wind

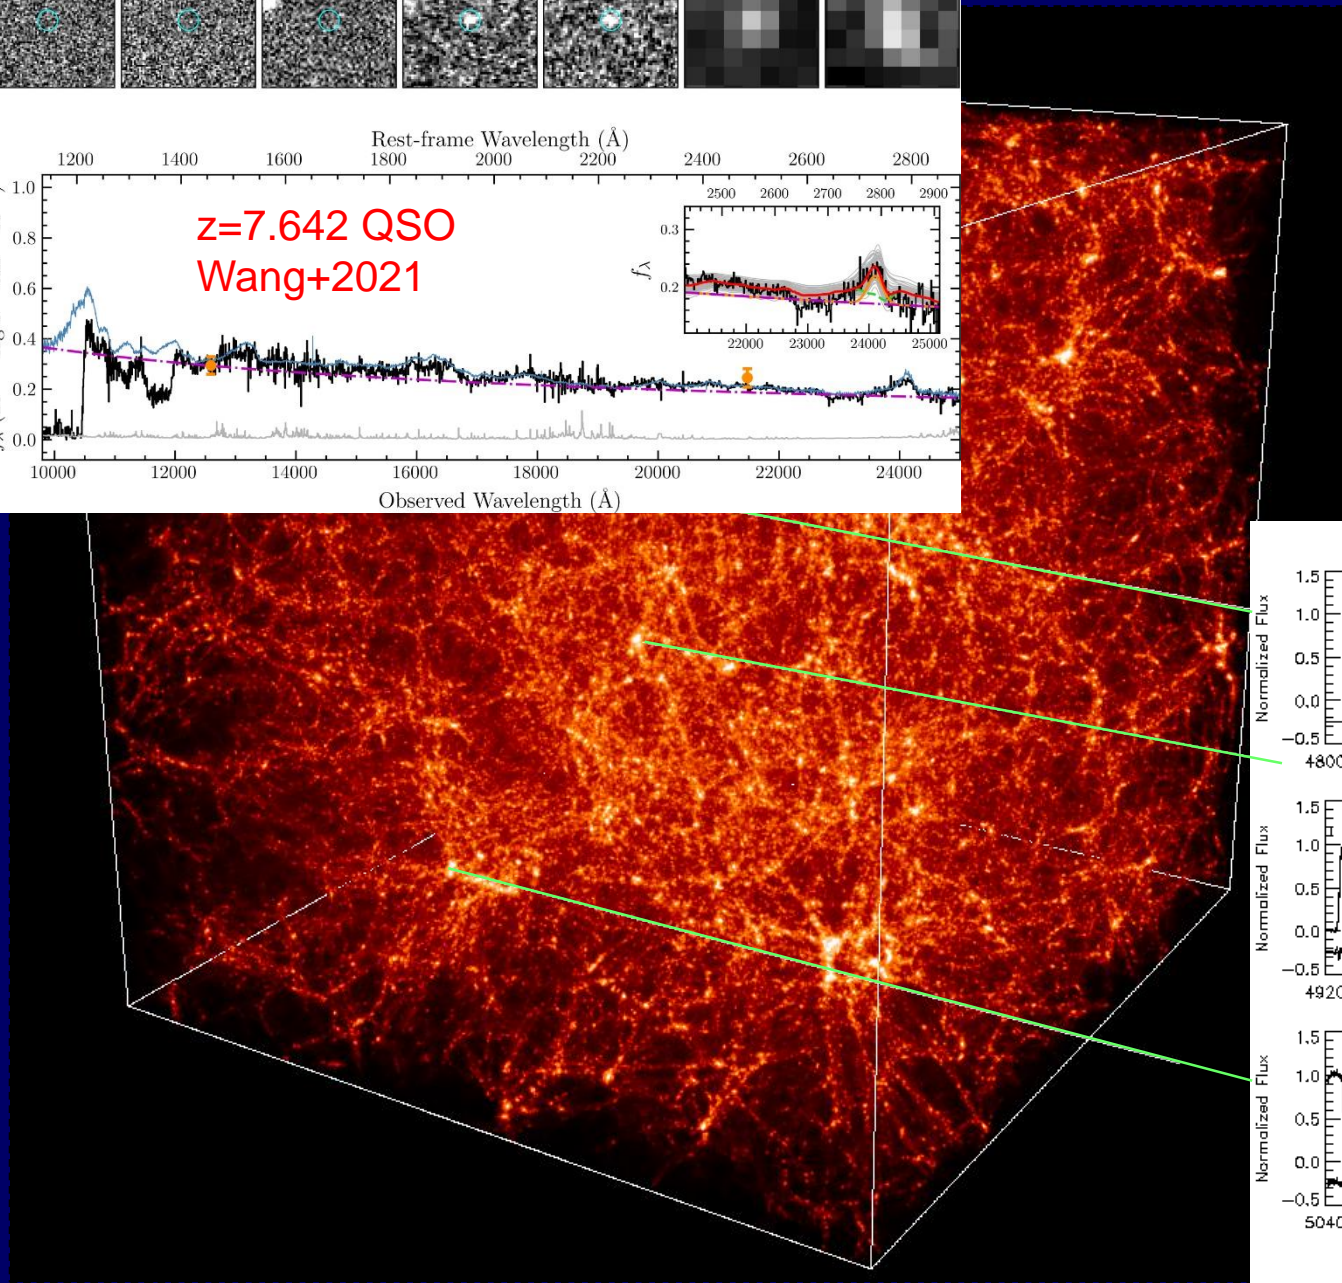

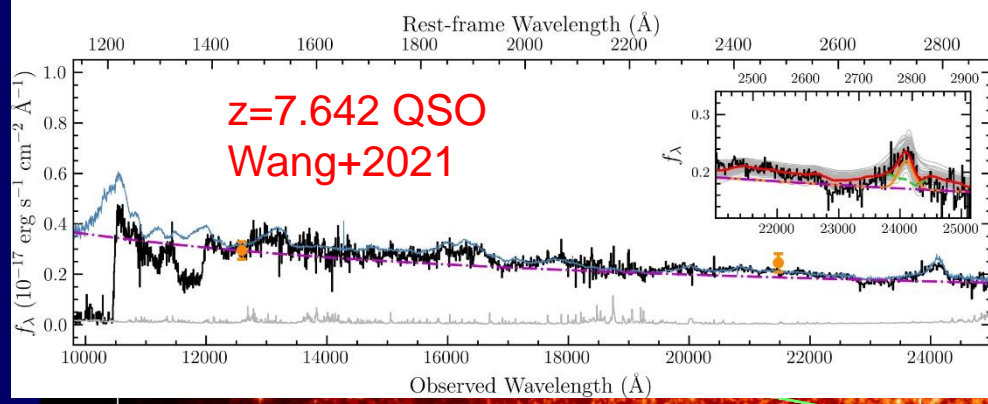

Density - temperature

- Big Bang
- Recombination
- Dark Ages
- Formation of stars, galaxies and QSOs
- Reheating and reionization

## A UVES absorption spectrum

A beam of light coming from a distant quasar passes through numerous intervening gas clouds in galaxies and in intergalactic space. These clouds of primeval matter subtract specific colours from the beam. The resulting 'absorption spectrum', recorded by the VLT UV-Visual Echelle Spectrograph (UVES), is used to determine the distances, physical properties and chemical composition of the invisible clouds.

# IGM - absorption lines

A unique and independent source of information between the CMB, at  $z \sim 1000$ , and the large scale distribution of galaxies

# IGM - Absorption Lines - Goals

- What were the physical conditions of the primordial Universe?
- What fraction of the matter was in a diffuse medium and how early did it condense in clouds?
- Where are most of the baryons at the various redshifts?
- How early and in what amount have metals been produced?
- When and how, after the Dark Ages following recombination, did the Universe get reionized?
- What was the typical radiation field, how homogenous, and what was producing it?
- Which constraints on cosmology & types of DM (e.g.  $\nu$ ) are derived from the IGM LSS?
- Does the SBBN correctly predict primordial element abundances and CMB T evolution?
- Do fundamental constants of physics (e.g.  $\alpha$ ,  $\mu$ ) vary with time?

# Evaluation

- 1 question per person at the beginning of the lecture on the topics of the previous lecture
- (Final) discussion of 1 (or more) papers – possibly recent - on a topic of the course with a short (~20 min) presentation.
