In the proximity of the
Sun (~ 3 AU), comets
deliver these organic
residues. Travelling
through interplanetary
medium, they are further
exposed to the radiation.

Could they contribute to
the bio-chemical
evolution of the Earth??

OUR AIM

We already investigated (in the laboratory) the effects of the ion irradiation on the organic residues (*Palumbo et al, 2004*)

Now we want to study the effects of the solar UV photons on the organic residues by comparing them with the residues exposed to Lyman-alpha photons in our laboratory.

In addition to the 30 samples for the PSS project, we have produced similar ones in order to...

- Simulate, in our laboratory, the solar vacuum UV irradiation on the refractory residues
- Study the temporal (natural) evolution of the organic residues stored in our laboratory at room temperature and pressure

Analysis on the Organic Residues

- WORK STILL IN PROGRESS -

- Laboratory UV irradiation of the refractory residues

UV lamp already mounted.
Ready to start!

• Collection of several IR spectra in a time frame of about 600 days

• Investigation how the intensity of the bands naturally evolve over time

IMPORTANCE

To disentangle the effects of the solar radiation from the natural degradation.

3200 cm^{-1} band:

only little variations over the time.

The intensity variations do not show a clear trend.

2200 cm^{-1} band:

clear, gradual reduction in intensity over time.

For all the sample thickness, the 2200 cm^{-1} band decays over time. However, we need further data to conclude if :

- the band is going to become stable
- OR
- the band is going to disappear

EXPERIMENT

- Our organic samples are flying on board to the ISS since July 2014 and they will come back on March 2016
- We are ready to begin the UV irradiation of the refractory residues in our laboratory
- We need to collect further spectra to conclude if the 2200 cm^{-1} band naturally disappears over the time or not
- In any case, the other bands in our refractory samples do not show natural degradation over time
- We have planned to study the temporal evolution of our samples storing them at lower temperature ($\sim 70\text{ K}$)

Photochemistry on Space Station: a study of the effects of the solar electromagnetic radiation on organic refractory samples

Thank you for your attention!

Goal of the experiment

To better clarify the goal of the experiment, we show a comparison of the IR spectra of one of our residue with those of two ultracarbonaceous Antarctic meteorites (Dartois et al., 2013) thought to have been originated in the outer solar system

**No fit,
but
similar
bands!**

Photochemistry on the Space Station (PSS) Experiment

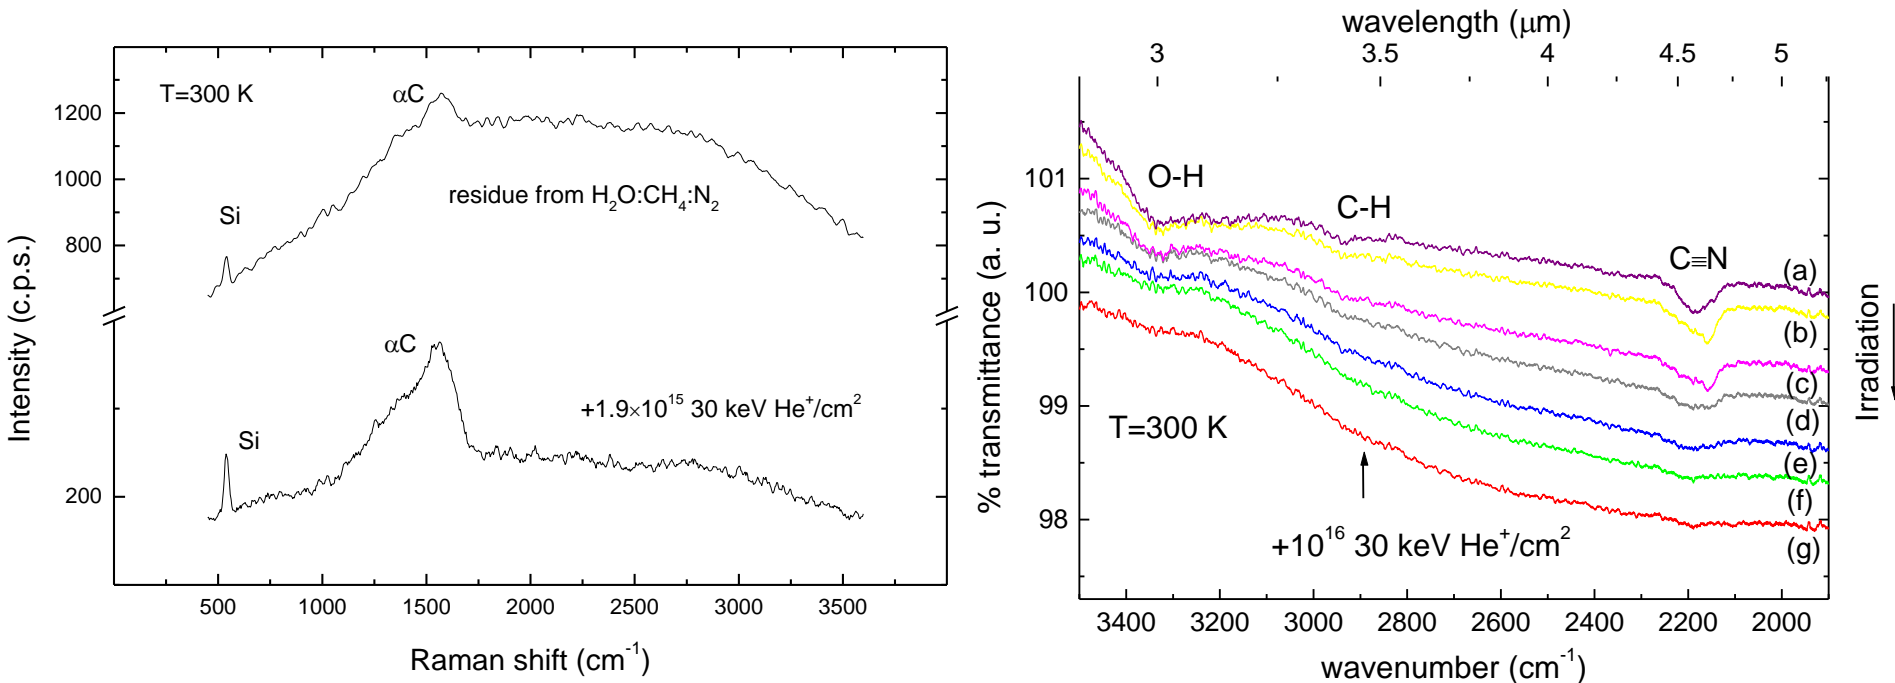

Contribution of the LAsp - Catania:

#10 190 nm thick
#10 130 nm thick
#10 65 nm thick

} 30 organic samples on MgF_2 windows

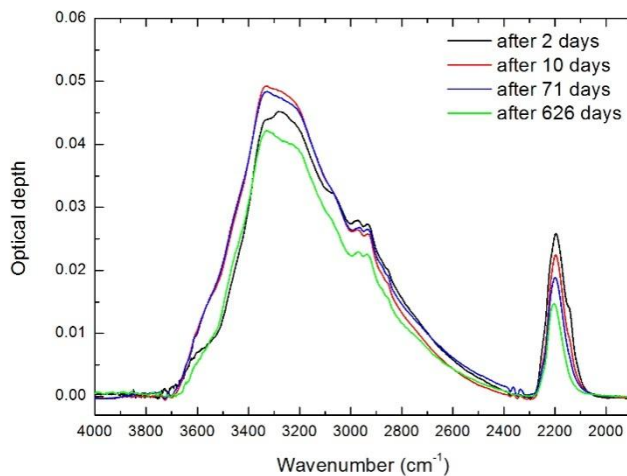

We already investigated (in the laboratory) the effects of the ion irradiation on the organic residues: the intensity of all infrared absorption features decreases.

Raman spectroscopy shows that ion irradiation causes a modification of the structure of the samples which evolve towards an amorphous carbon.
(Palumbo et al, 2004)
